Homework #3

Sam Fleischer

November 4, 2016

Problem 1

For the age-structured logger head model do the following:

(a) Find the dominant eigenvalue λ, the vector w of reproductive values, an the stable stage distribution v. Plot these and discuss what insights one can gleam from these bar plots that aren't apparent in the 7-stage matrix model used by Crose et al. (1987)

(b) Use w, v, and λ to predict the densities of all ages in 20 years if currently the loggerhead population consists of only $10,000$ hatchlings. Simulate the full matrix model, plot the simulation, and compare the predictions at year 20 by plotting them side-by-side using the barplot command. Repeat both computations for 100 years and discuss.

(c) Compute and plot the elasticities of λ to survivorship and fecundity of all age classes. Compare and contrast these elasticities to the Crouse et al. (1987) paper.

(a) The seven stages of this model are

(a) Hatchlings
(b) Yearlings
(c) Juveniles
(d) Sub-Adults
(e) First-Time Reproducers
(f) Remigrants
(g) Mature Adults

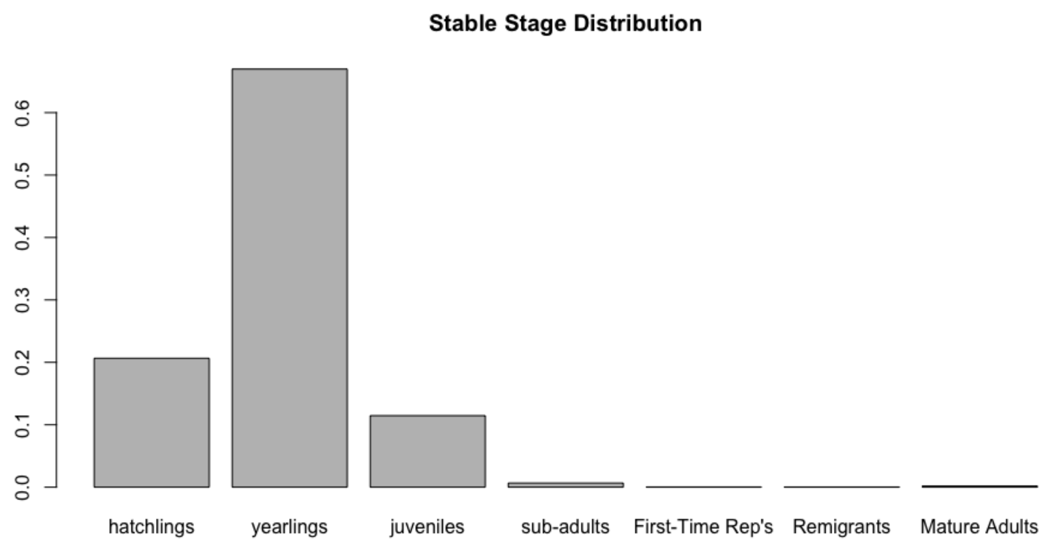
The matrix describing their population shifts after one year are given by

$$A = \begin{pmatrix} 0 & 0 & 0 & 0 & 127 & 4 & 80 \\ 0.6747 & 0.737 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0.0486 & 0.6610 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.0147 & 0.6907 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.0518 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0.8091 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.8091 & 0.8089 \end{pmatrix}$$

The largest eigenvalue of this matrix, $\lambda \approx 0.945$, corresponds to the eigenvector

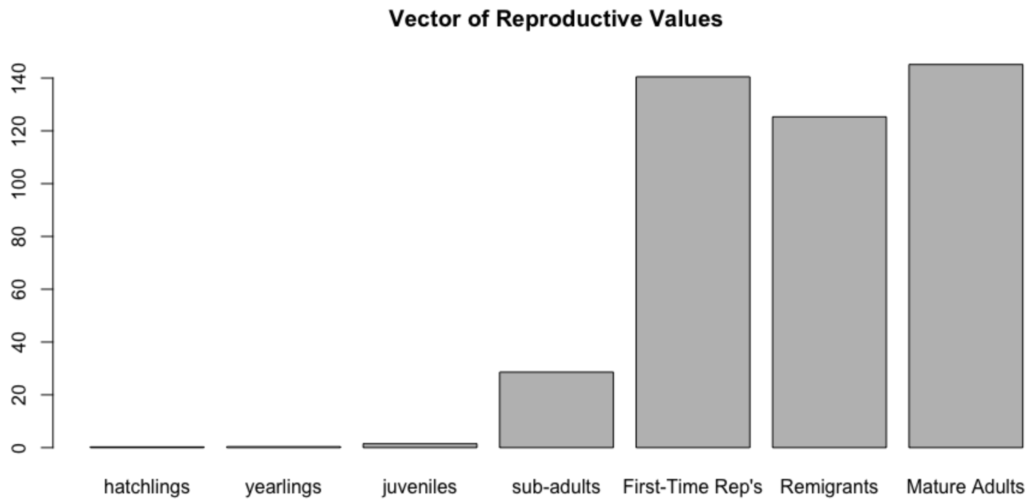
$$v \approx \begin{bmatrix} 0.2065048418 \\ 0.6697503241 \\ 0.1145997020 \\ 0.0066237138 \\ 0.0003630657 \\ 0.0003108432 \\ 0.0018475094 \end{bmatrix}$$

This is the stable stage distribution, i.e. as $t \to \infty$, $\dfrac{N_t}{\|N_t\|_1} \to v$ with probability 1.



The vector of reproductive values w is the scaled eigenvector of A^T corresponding to the largest eigenvector. The scaling constant is $\dfrac{1}{\|v * w\|_1}$ where $*$ represents component-wise multiplication. We find

$$w \approx \begin{bmatrix} 0.2469775 \\ 0.3459336 \\ 1.4807593 \\ 28.6109872 \\ 140.4760701 \\ 125.3097224 \\ 145.1410949 \end{bmatrix}.$$

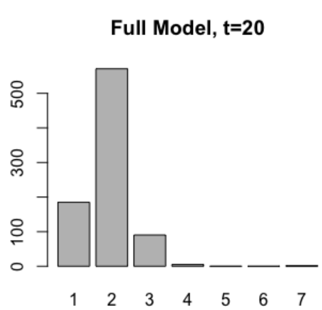


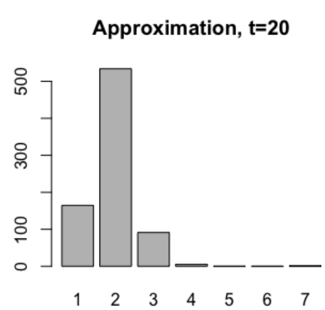
The stable-stage distribution shows us what we should expect in the long term if A stays constant over time. That is, that ~ 67% of individuals in the population should be yearlings, ~ 20.7% should be hatchlings, ~ 11.5% should be juveniles, and the rest < 1% are sub-adults, first-time reproducers, re-migrants, and mature adults. Naïvely, this might lead us to focus conservation efforts on the hatchlings and yearlings to preserve the distribution. However, the vector of reproductive values tells us the relative value of each of these stages in terms of what they contribute to future generations. The mature adults, remigrants, and first-time reproducers have the highest reproductive value, and thus are the most important to reproduction. Conservation efforts, then, should be focused on preserving what few adults are in the population. Even though many hatchlings are lost, they have little to no reproductive value anyway. This is intuitive since based on the matrix A, it is highly unlikely that an individual makes it to adulthood. If the individual makes it to adulthood, however, it is extremely valuable in terms of how many new individuals it can produce.

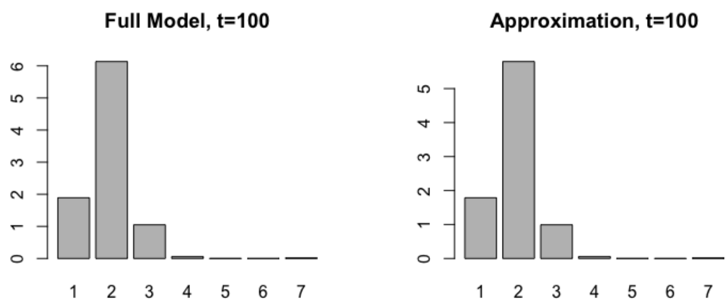
(b) Using $N_0 = \begin{bmatrix} 10,000 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}^T$, and λ, v, w found above, we use the approximation

$$N_t \approx 10^4 w_1 \lambda^t v$$

where $w_1 = 0.2469775$ is the reproductive number of the hatchlings. Here are the plots for $t = 20$ and $t = 100$:







For $t = 20$, there is an error of about 37 in the approximation of the yearlings, about 20 in the approximation of the hatchlings, and about 1 in the approximation of the juveniles. All other errors are $\mathcal{O}(0.1)$. For $t = 100$, all errors are $\mathcal{O}(0.1)$ (the largest error is in the approximation of the hatchlings: about 0.34).

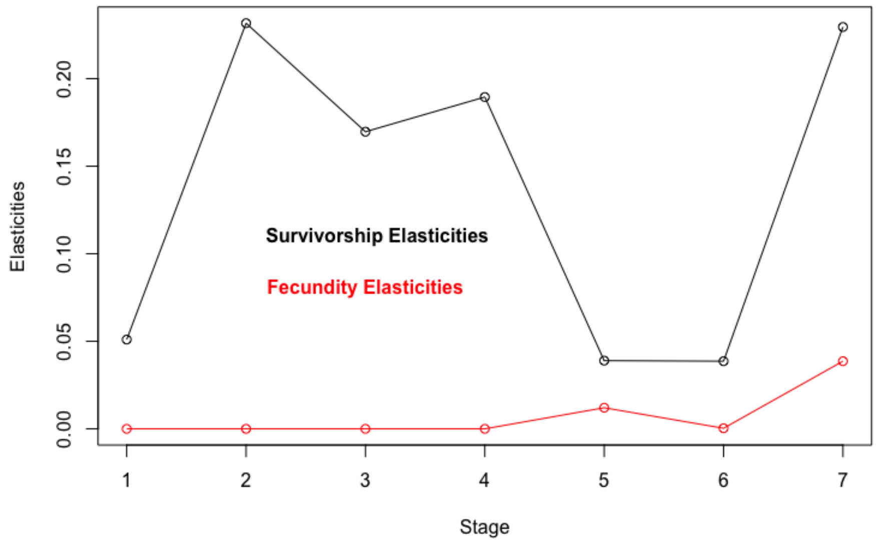
(c) Sensitivities of λ to changes in A (notated S) are given by the outer product of w with v, that is

$$S = \begin{pmatrix} w_1 \\ w_2 \\ w_3 \\ w_4 \\ w_5 \\ w_6 \\ w_7 \end{pmatrix} \begin{pmatrix} v_1 & v_2 & v_3 & v_4 & v_5 & v_6 & v_7 \end{pmatrix} = \begin{pmatrix} w_1v_1 & w_1v_2 & w_1v_3 & w_1v_4 & w_1v_5 & w_1v_6 & w_1v_7 \\ w_2v_1 & w_2v_2 & w_2v_3 & w_2v_4 & w_2v_5 & w_2v_6 & w_2v_7 \\ w_3v_1 & w_3v_2 & w_3v_3 & w_3v_4 & w_3v_5 & w_3v_6 & w_3v_7 \\ w_4v_1 & w_4v_2 & w_4v_3 & w_4v_4 & w_4v_5 & w_4v_6 & w_4v_7 \\ w_5v_1 & w_5v_2 & w_5v_3 & w_5v_4 & w_5v_5 & w_5v_6 & w_5v_7 \\ w_6v_1 & w_6v_2 & w_6v_3 & w_6v_4 & w_6v_5 & w_6v_6 & w_6v_7 \\ w_7v_1 & w_7v_2 & w_7v_3 & w_7v_4 & w_7v_5 & w_7v_6 & w_7v_7 \end{pmatrix}.$$

The elasticities of λ to changes in A (notated E) are given by $S * A * \frac{1}{\lambda}$, that is

$$E = \frac{1}{\lambda} \begin{pmatrix} a_{11}w_1v_1 & a_{12}w_1v_2 & a_{13}w_1v_3 & a_{14}w_1v_4 & a_{15}w_1v_5 & a_{16}w_1v_6 & a_{17}w_1v_7 \\ a_{21}w_2v_1 & a_{22}w_2v_2 & a_{23}w_2v_3 & a_{24}w_2v_4 & a_{25}w_2v_5 & a_{26}w_2v_6 & a_{27}w_2v_7 \\ a_{31}w_3v_1 & a_{32}w_3v_2 & a_{33}w_3v_3 & a_{34}w_3v_4 & a_{35}w_3v_5 & a_{36}w_3v_6 & a_{37}w_3v_7 \\ a_{41}w_4v_1 & a_{42}w_4v_2 & a_{43}w_4v_3 & a_{44}w_4v_4 & a_{45}w_4v_5 & a_{46}w_4v_6 & a_{47}w_4v_7 \\ a_{51}w_5v_1 & a_{52}w_5v_2 & a_{53}w_5v_3 & a_{54}w_5v_4 & a_{55}w_5v_5 & a_{56}w_5v_6 & a_{57}w_5v_7 \\ a_{61}w_6v_1 & a_{62}w_6v_2 & a_{63}w_6v_3 & a_{64}w_6v_4 & a_{65}w_6v_5 & a_{66}w_6v_6 & a_{67}w_6v_7 \\ a_{71}w_7v_1 & a_{72}w_7v_2 & a_{73}w_7v_3 & a_{74}w_7v_4 & a_{75}w_7v_5 & a_{76}w_7v_6 & a_{77}w_7v_7 \end{pmatrix}.$$

The elasticities associated with fecundity are given by the elements in the first row, which correspond to how many births do individuals in any given stage give. The elasticities associated with survivorship are given by the sum of the entries on the diagonals and the sub-diagonals since surviving individuals either stay in their class or move on to the next class. Here is the result:



This shows that λ is the most sensitive to survivorship and fecundity of the subclass of mature adults, which is consistent with our analysis of the vector of reproductive values w. In Fig. 3 in Crouse et al. 1987, she separates the elasticities of survival while staying in the same stage, labeled P_i, with the elasticities of survival with growth, labeled G_i. My figure above maches perfectly with Crouse's. My survivorship elasticities are the component-wise sum of Crouse's P_i and G_i, as shown in her figure below.

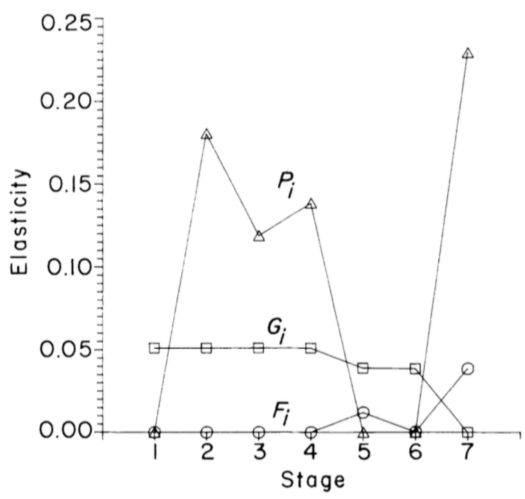


FIG. 3. The elasticity, or proportional sensitivity, of λ_m to changes in fecundity F_i (○), survival while remaining in the same stage P_i (△), and survival with growth G_i (□). Because the elasticities of these matrix elements sum to 1, they can be compared directly in terms of their contribution to the population growth rate r.
